FOLIATIONS BY CURVES UNIQUELY DETERMINED BY MINIMAL SUBSCHEMES OF ITS SINGULARITIES

ANTONIO CAMPILLO AND JORGE OLIVARES

Dedicated to the memory of Professor Egbert Brieskorn

Abstract. It is well-known that a foliation by curves of degree greater than or equal to two, with isolated singularities, in the complex projective space of dimension greater than or equal to two, is uniquely determined by the scheme of its singular points. The main result in this paper is that the set of foliations which are uniquely determined by a subscheme (of the minimal possible degree) of its singular points, contains a nonempty Zariski-open subset. Our results hold in the projective space defined over any algebraically closed ground field.

1. Introduction and statement of the results

Let $\mathbb{P}^n = \mathbb{P}^n_K$ be the projective space of dimension $n \geq 2$ over an algebraically closed ground field $K$ and let $\mathcal{O}_{\mathbb{P}^n}, \Theta_{\mathbb{P}^n}$ and $\mathcal{H}$ denote its structure, tangent and hyperplane sheaves. For an $\mathcal{O}_{\mathbb{P}^n}$-sheaf $\mathcal{E}$, we will write $\mathcal{E}(d)$ for $\mathcal{E} \otimes \mathcal{H}^\otimes d$, if $d \geq 0$ and $\mathcal{E} \otimes (\mathcal{H}^\ast) \otimes |d|$, if $d < 0$.

Let

$$E = E(n, r - 1) = H^0(\mathbb{P}^n, \Theta_{\mathbb{P}^n}(r - 1)), \quad \text{and} \quad e = e(n, r - 1) = \dim_K E.$$ (1.1)

A foliation by curves with singularities (or simply a foliation in the sequel) of degree $r$ on $\mathbb{P}^n$ is the class $[s] \in \mathbb{P}E$ of a global section $s \in E$. We denote the scheme of zeroes of $[s]$ by $([s])_0$. We say $[s]$ has isolated singularities if $\dim ([s])_0 = 0$ and we say is non-degenerate, if it has isolated singularities and $([s])_0$ is reduced.

It is known that a foliation $[s]$ of degree $r \geq 2$ in $\mathbb{P}^n$ with isolated singularities is uniquely determined by $([s])_0$, in the sense that $([s'])_0 \supseteq ([s])_0$ for some $[s']$ of degree $r$, implies that $[s'] = [s]$ (that is, $s' = \lambda \cdot s$, for some $\lambda \in K^\ast$). For $K = \mathbb{C}$, the result was first established for $[s]$ non-degenerate, in [10] and the general statement was later obtained in [6]. For an algebraically closed ground field $K$, it was established for $n = 2$ in [5], and the general version was finally established in [1].

Let $[s]$ be a foliation of degree $r > 2$ in $\mathbb{P}^n$, with isolated singularities. At least if $K = \mathbb{C}$, there always exist proper subschemes $Z \subset ([s])_0$ such that $[s]$ is uniquely determined by $Z$ in the sense that $([s'])_0 \supseteq Z$ for some $[s']$ of degree $r$, implies that $[s'] = [s]$. This is the content of Proposition 1.1 below. Given $n \geq 2$, and $r \geq 2$, the degree of such subschemes $Z$ is bounded from below by a certain integer $m(n, r - 1)$ which we compute in Lemma 1.2 below. The main result of the paper, Theorem 1.3 below, is that the set of foliations $[s]$ (with isolated singularities or not) which are uniquely determined by a $Z \subset ([s])_0$ having this minimal degree contains a nonempty Zariski open subset of $\mathbb{P}E$.

Our main reference is [3]. Our notation comes from there.

Let $U \subset \mathbb{P}^n$ be an open affine that trivializes $\Theta_{\mathbb{P}^n}(r - 1)$, and let $p \in U$. The restriction of a section $s \in E$ to $U$ is an affine vector field $\hat{s} = (s^1, \ldots, s^n)$. The multiplicity $\mu(s, p)$ of $s$ at $p$, is

2000 Mathematics Subject Classification. Primary 32S65; Secondary 32L10.
the intersection multiplicity at $p$ of the hypersurfaces $s^j = 0$, i.e., the vector-codimension in the local ring $\mathcal{O}_{P^n,p}$ of the ideal generated by \{s_j\}_j=1:

$$\mu(s, p) = \dim_{K} \mathcal{O}_{P^n,p} / (s^1, \ldots, s^n) : \mathcal{O}_{P^n,p}.$$ 

(1.2)

It is clear that $\mu(s, p) = \mu(\lambda s, p)$, for every $\lambda \in K^{*}$, so that $\mu([s], p)$ is well-defined and, moreover, that $p$ is a singularity of $[s]$ if and only if $\mu(s, p) \neq 0$ and that $\mu(s, p)$ is non-zero and finite if and only if $p$ is an isolated singularity of $[s]$. Moreover, $[s]$ is non-degenerate if and only if $\mu([s], p) = 1$, for every $p \in ([s])_0$.

It follows from the Euler sequence

$$0 \rightarrow \mathcal{O}_{P^n}(r - 1) \rightarrow \mathcal{O}_{P^n}(r)^{\oplus(n + 1)} \rightarrow \mathcal{O}_{P^n}(r - 1) \rightarrow 0,$$

that $e = (n + 1)\left(\frac{n + r}{n}\right) - \left(\frac{n + r - 1}{n}\right)$ and that a foliation $[s]$ with isolated singularities has

$$\text{deg}([s])_0 = e_n(\Theta_{P^n}(r - 1)) = \sum_{j=0}^{n} r^j$$

zeroes, counting multiplicities.

The subsets $\mathcal{U}_{ad} \subset \mathcal{U}_0$ of foliations which are non-degenerate resp. have isolated singularities are both non-empty Zariski-open in $\mathbb{P}_E$.

The sheaf of ideals of a closed subscheme $Z \subset \mathbb{P}^n$ will be denoted by $I_Z$. For a zero-dimensional subscheme $Y \subset \mathbb{P}^n$, the space of sections $H^0(\mathbb{P}^n, \Theta_{P^n} \otimes I_Y(r - 1))$ that vanish on $Y$ will be denoted by

$$E_Y = H^0(\mathbb{P}^n, \Theta_{P^n} \otimes I_Y(r - 1)), \text{ with } e_Y = \dim_{K} E_Y.$$ 

If $Y$ has degree $\omega$ and it is reduced, we may consider it as a point in the symmetric product $S^Y \mathbb{P}^n$.

Our first result generalizes [7, Corollary 3.3]:

**Proposition 1.1.** Let $n \geq 2$ and $r \geq 2$ be integers, let $[s]$ be a foliation with isolated singularities of degree $\omega$ in the complex projective space $\mathbb{P}^n$, and let $s_1 \in H^0(\mathbb{P}^n, \Theta_{P^n}(r - 1))$ be a section that vanishes at a subscheme $Z' \subset ([s])_0$ whose degree satisfies $\text{deg}Z' \geq \text{deg}([s])_0 - (n(r - 1) - 1)$. Then $s_1 = \lambda s$ for some $\lambda \in \mathbb{C}^{*}$ and hence $[s_1] = [s]$.

**Lemma 1.2.** Let $n \geq 2$ and $r \geq 2$, be integers, let $e$ be given by (1.1). Let $\omega = \alpha(n, r - 1) = \left[\frac{e - 1}{n}\right]$ be the integral part of the number between brackets and let $0 \leq \rho \leq n - 1$ be the unique integer such that $e - 1 = n \cdot \omega + \rho$.

Let $Y$ be a zero-dimensional closed subscheme of $\mathbb{P}^n$ of degree $\omega$, and assume that

$$e_Y = H^0(\mathbb{P}^n, \Theta_{P^n} \otimes I_Y(r - 1)) = 1.$$ 

Then $\omega \geq \omega$, if $\rho = 0$ and $\omega \geq \omega + 1$, if $1 \leq \rho \leq n - 1$. In consequence, the minimal possible degree $m(n, r - 1)$ of a zero-dimensional subscheme $Y \subset ([s])_0$ such that $e_Y = 1$ is

$$m(n, r - 1) = \begin{cases} \omega & \text{if } \rho = 0, \\ \omega + 1 & \text{if } 1 \leq \rho \leq n - 1. \end{cases}$$

**Theorem 1.3.** Let $n \geq 2$ and $r \geq 2$, be integers. Let $\omega = \left[\frac{e - 1}{n}\right]$ and $0 \leq \rho \leq n - 1$ be as in Lemma 1.2, and $e_Y$, as in (1.4),

(a) If $\rho = 0$, then the subset

$$B_{\omega} = \{[s] \in \mathbb{P}E \mid \exists Y \in S^Y \mathbb{P}^n \text{ with } Y \subset ([s])_0 \text{ and } \mathbb{P}E_Y = \{[s]\}$$

contains a nonempty Zariski-open subset $V_\omega$ of $\mathbb{P}E$. 

(b) If \(1 \leq \rho \leq n - 1\), then the subset
\[
B_{\omega+1} = \{ [s] \in \mathbb{P}E \mid \exists Y^1 \in S^{\omega+1}\mathbb{P}^n \text{ with } Y^1 \subset ([s])_0 \text{ and } \mathbb{P}E_{Y^1} = ([s]) \}
\]
contains a nonempty Zariski-open subset \(V_{\omega+1}\) of \(\mathbb{P}E\).

It follows in particular that for \(U = U_{nd}\) or \(U_0\) and \(V = V_\omega\) or \(V_{\omega+1}\) (depending on (a) or (b) above, resp.), the subsets \(U \cap V\) are nonempty Zariski-open subsets of \(\mathbb{P}E\).

2. The proofs

Proof of Proposition 1.1. Consider \(X = \mathbb{P}^n, E = \Theta_{\mathbb{P}^n}(r - 1), Z = (s)_0\) and a fixed divisor \(L\) of degree \(\ell\) on \(\mathbb{P}^n\). It is then clear that \(\det E = \Theta_{\mathbb{P}^n}(nr + 1)\) and that \(F\) in the complete linear system \([\det E - L]\) has degree \(nr + 1 - \ell = r + 1\) if and only if \(\ell = (n - 1)r\). Hence, the linear system \([K_{\mathbb{P}^n} + L]\) is ample \([14, \text{Definition 1.1}]\) if and only if \(k = n(r - 1) - r\). It follows from \([14, \text{Theorem 1.2}]\) that any \(F \in \) \([\det E - L]\) passes through a subscheme \(Z^r \subset (s)_0\) of degree \(\deg Z^r \geq \deg(s)_0 - (n(r - 1) - r)\) necessarily passes through all of \((s)_0\). Now, for an \(s_1\) as in the statement, each of its components satisfies the conditions of the \(F\) above, and hence \((s)_0 \geq (s)_0\).

This, together with \([6, \text{Theorem 3.5}]\), gives the desired conclusion.

Proof of Lemma 1.2. Let \(Y \in S^y\mathbb{P}^n\) be a zero-dimensional closed subscheme of \(\mathbb{P}^n\) of degree \(y\), with sheaf of ideals \(I_Y\). We have a short exact sequence of sheaves
\[
0 \to I_Y \to \mathcal{O}_{\mathbb{P}^n} \to \mathcal{O}_Y \to 0.
\]
It follows that \(h^2(\mathbb{P}^n, I_Y(j)) = 0\), for \(n = 2\) and \(j \geq -2\) from \([9, \text{Lemma 2.4}]\) and for \(n > 2\) and every \(j\), from Serre’s computations.

Now, consider the short exact sequence obtained by tensoring \((1.3)\) with the sheaf \(I_Y\) above and its associated long exact cohomology sequence. Using an appropriate twist of \((2.1)\), it follows easily that
\[
h^0(\mathbb{P}^n, \Theta_{\mathbb{P}^n} \otimes I_Y(r - 1)) - h^1(\mathbb{P}^n, \Theta_{\mathbb{P}^n} \otimes I_Y(r - 1)) = h^0(\mathbb{P}^n, \Theta_{\mathbb{P}^n} \otimes I_Y(r - 1)) - n \cdot y, \text{ or}
\]
\[
e_Y - e_Y^1 = e - n \cdot y, \text{ where } e_Y^1 = h^1(\mathbb{P}^n, \Theta_{\mathbb{P}^n} \otimes I_Y(r - 1)).
\]

For a closed point \(p \in \mathbb{P}^n\), the (linear) space \(E_p\) has codimension \(n\) in \(\mathbb{P}E\). Hence, the term \(e_Y^1 = h^1(\mathbb{P}^n, \Theta_{\mathbb{P}^n} \otimes I_Y(r - 1))\) is equal to the number of dependent conditions imposed by the points of \(Y\) in \(E\).

Now assume \(e_Y = 1\).

It then follows from \((2.2)\) that \(n \cdot y - e_Y^1 = e - e_Y = e - 1 \leq n \cdot y\), and hence, \(\omega = \frac{e - 1}{n} \leq \frac{e - 1}{n} \leq y\), which is the first assertion. In the same vein, it is easy to see that if \(e_Y = 1\) and \(y = \omega\), then \(e_Y^1 = 0\) if and only if \(\rho = 0\).

On the other hand, if \(1 \leq \rho \leq n - 1\), then \(e - 1 = \omega \cdot n + \rho = e - e_Y = y \cdot n - e_Y^1\), hence \((y - \omega) \cdot n = (e_Y^1 - \rho)\). This equation cannot hold for \(y = \omega\) and hence \(y - \omega \geq 1\), which is the second assertion. We close by recalling that if \(y = \omega + 1\) and \(e_Y = 1\), then \(e_Y^1 = n - \rho > 0\), as is easy to see.

Proof of Theorem 1.3 (a). This is a straight-forward consequence of \([3, \text{Theorem 0.1}]\). The proof is included to fix our further notation.

For \(y \leq \omega = \omega(n, r - 1)\), let \(N_{y,k} = \{ Y \in S^y\mathbb{P}^n \mid e_Y = e - n \cdot y + k \}\). It follows that \(N_y = N_{y,0} \subset S^y\mathbb{P}^n\) is open (because it is the subvariety of \(Y \in S^y\mathbb{P}^n\) where \(e_Y\) attains its minimum value) and nonempty (because of \([3, \text{Theorem 0.1(a)}]\)). It is hence dense in \(S^y\mathbb{P}^n\) and \(\dim N_y = n \cdot y\).
Let
\[ S^y \mathbb{P}^n \xrightarrow{\Pi_1} S^y \mathbb{P}^n \times \mathbb{PE} \xrightarrow{\Pi_2} \mathbb{PE}, \]
be the product variety with canonical projections. Let \( A \) be the universal family of foliations of degree \( r - 1 \) from \( [10] \), and consider the variety
\[
Z_y = \{(Y, [s]) \in S^y \mathbb{P}^n \times \mathbb{PE} \mid A(p, [s]) = [s](p) = 0, \text{ for every } p \in Y\}
\]
\[
= \{(Y, [s]) \in S^y \mathbb{P}^n \times \mathbb{PE} \mid p \in ([s])_0, \text{ for every } p \in Y\}
\]
\[
= \{(Y, [s]) \in S^y \mathbb{P}^n \times \mathbb{PE} \mid Y \subset ([s])_0\}
\]
\[
= \{(Y, [s]) \in S^y \mathbb{P}^n \times \mathbb{PE} \mid [s] \in \mathbb{PE}_Y \} \subset S^y \mathbb{P}^n \times \mathbb{PE},
\]
with restrictions \( \Pi_1 = \hat{\Pi}_1|_{Z_y} : Z_y \rightarrow S^y \mathbb{P}^n \) and \( \Pi_2 = \hat{\Pi}_2|_{Z_y} : Z_y \rightarrow \mathbb{PE} \). Let
\[
Z_{y,0} = \Pi_1^{-1}(N_y) = \{(Y, [s]) \in Z_y \mid Y \subset N_y\}.
\]
\( Z_{y,0} \) is open in \( Z_y \). It is moreover irreducible and has the same dimension
\[ n \cdot y + e - n \cdot y - 1 = e - 1 \]
as \( \mathbb{PE} \) does, because all fibers \( \Pi_1^{-1}(Y) \) are irreducible and have the same dimension
\[ \dim \mathbb{PE}_Y = e - n \cdot y - 1 \]
(which is equal to zero, if \( y = \omega \) and \( \rho = 0 \)). Now consider the restrictions
\[ \Pi_1 = \Pi_1|_{Z_{y,0}} : Z_{y,0} \rightarrow N_y \subset S^y \mathbb{P}^n \]
and \( \Pi_2 = \Pi_2|_{Z_{y,0}} : Z_{y,0} \rightarrow \mathbb{PE} \) and recall that, set-theoretically,
\[ \Pi_2(Z_{y,0}) = \{[s] \in \mathbb{PE} \mid \exists Y \in N_y \text{ such that } Y \subset ([s])_0\}. \]
\( \Pi_2 \) is a regular map between irreducible varieties of the same dimension which we claim to be dominant (the closure of its image \( \overline{\Pi_2(Z_{y,0})} \) is \( \mathbb{PE} \) or \( B = \Pi_2(Z_{y,0}) \) is contained in no hypersurface). Assuming this for a moment, we may finish the proof applying \([11, \text{ Proposition 6.4.1}]\) which shows the existence of a subset
\[ V_y \subset B \]
which is open and dense in \( \overline{B} = \mathbb{PE} \) and the desired conclusion follows taking \( y = \omega \) in (2.4).

We prove that \( \Pi_2 \) is dominant by contradiction: If it were not, then we may assume that \( \overline{B} = C \) is an irreducible hypersurface and there exists a nonempty subset \( V' \subset B \) open and dense in \( C \) such that \( \dim \Pi_2^{-1}([s_0]) = \dim Z_{y,0} - \dim C = 1 \), for every \([s_0] \in V'\). Since
\[ \Pi_2^{-1}([s_0]) = \{(Y, [s]) \mid Y \in N_y \text{ and } Y \subset ([s_0])_0\}, \]
the condition \( \dim \Pi_2^{-1}([s_0]) = 1 \) implies that some \( p \in Y \) is a non-isolated singularity of \([s_0]\). Since \( V' = C \cap W \) for some non-empty open set \( W \subset \mathbb{PE} \), it follows that \( \Pi_2^{-1}(V') \) is a non-empty open subset of the irreducible \( Z_{y,0} \), hence it is dense. Consider a \( Y \in N_y \) from (2.5). Then \( \Pi_2^{-1}(V') \cap (Y \times \mathbb{PE}_Y) \neq \emptyset \) is therefore open and dense. This implies that
\[ \{[s] \in \mathbb{PE}_Y \mid \exists p \in Y \text{ with } \dim_p([s])_0 = 1\} \]
is non-empty and open, therefore is dense in \( \mathbb{PE}_Y \).

On the other hand, for \( Y \in N_y \), the subspace \( \mathbb{E}_Y \) is the transversal intersection \( \bigcap_{p \in Y} \mathbb{E}_p \) of the linear subspaces \( \mathbb{E}_p \subset \mathbb{E} \) and \( \mathbb{E}_p^1 = \{s \in \mathbb{E} \mid \mu([s], p) = 1\} \) is open and dense in \( \mathbb{E}_p \) (by \([10, \text{ Lemma 1.2}]\), so that
\[ \bigcap_{p \in Y} \mathbb{E}_p^1 \subset \mathbb{E}_Y \] is also open and dense in \( \mathbb{E}_Y \),
\[
\mathbb{P}(\bigcap_{e \in Y} \mathcal{E}_e^1) \subset \mathbb{P}E_Y
\]
is open and dense.

These two open sets of \( \mathbb{P}E_Y \) should have non-empty intersection, which is clearly absurd. This finishes the proof of Theorem 1.3 (a).

To prepare for the proof of Theorem 1.3 (b), we keep the previously introduced notation. We still consider \( y \) and the unique \( e \) with \( 1 \leq e \leq n - 1 \) such that \( e - 1 = n \cdot \omega + e \). It follows that \( e_\nu = e + 1 \) if \( Y \in N_\omega \). For each such \( Y \), let \( \mathbf{s} = \{ s_0, \ldots, s_e \} \) be a \( \mathbb{K} \)-basis of \( E_Y \); These sections define a vector-bundle map

\[
\phi = \phi_\mathbf{s} : T \longrightarrow \Theta_{\mathbb{P}^n}(r - 1)
\]
from the trivial vector bundle \( T \) of rank \( r + 1 \). In an open affine \( U \subset \mathbb{P}^n \) that trivializes both \( T \) and \( \Theta_{\mathbb{P}^n}(r - 1) \), \( \phi \) is represented by the matrix

\[
A = A_\mathbf{s} = [s_0, \ldots, s_e] \in M_{n \times (r + 1)}(\mathcal{O}_{\mathbb{P}^n}(U))
\]
whose column \( \delta_i = (s_1^i, \ldots, s_n^i) \in \mathcal{O}_{\mathbb{P}^n}(U)^{\mathbb{P}^n} \) is the restriction of \( s_i \) to \( U \), for \( i = 0, \ldots, e \).

On the other hand, let \( M = M_{n \times (r + 1)}(\mathbb{K}) \) be the affine variety of matrices with \( n \) rows and \( (r + 1) \) columns with coefficients in \( \mathbb{K} \). It is well-known (see [4]) that the subvariety \( M_\rho \) of matrices \( A \in M \) with \( \text{rk}A \leq \rho \) is irreducible and has codimension \( n - \rho \) in \( M \). This means that the ideal \( \mathcal{I}_\rho \) of \( M_\rho \) is generated by some \( n - \rho \) (maximal) minors

\[
A^J \subset A \text{ of size } |J| = r + 1,
\]
and \( M_\rho \) is (arithmetically) Cohen-Macaulay. The matrix \( A_\mathbf{s} \) corresponds to a morphism \( f : U \longrightarrow M; x \mapsto A_\mathbf{s}(x) \), and \( U_{\rho + 1} = f^{-1}(M_\rho) \) is independent of the trivialization chosen. This allows to define the degeneracy locus \( D_{\rho + 1}(\mathbf{s}) \) of the collection of sections \( \mathbf{s} \) by

\[
U_{\rho + 1} = D_{\rho + 1}(\mathbf{s}) \cap U
\]
(see [2, II, §4]). It is clear form this construction that

\[
D_{\rho + 1}(\mathbf{s}) = \{ p \in \mathbb{P}^n \mid (s_0 \land \cdots \land s_e)(p) = 0 \}, \text{ and that } \text{codim}D_{\rho + 1}(\mathbf{s}) \leq n - \rho.
\]
Similarly, we have

\[
D_\rho(\mathbf{s}) = \{ p \in \mathbb{P}^n \mid (s_{i_1} \land \cdots \land s_{i_p})(p) = 0, \text{ for every } \{ i_1, \ldots, i_p \} \subset \{ 0, \ldots, \rho \} \}.
\]

Our interest in these degeneracy loci comes from the following facts:

**Lemma 2.1.** Let \( n \geq 2 \) and \( r \geq 2 \), and assume that \( e - 1 \equiv \rho \mod n \), with \( 1 \leq \rho \leq n - 1 \). Let \( Y \in N_\omega \) and let \( \mathbf{s} = \{ s_0, \ldots, s_{e} \} \) be a \( \mathbb{K} \)-basis of \( E_Y \). Then \( D_{\rho + 1}(\mathbf{s}) \) is the locus of singular points \( p \in \mathbb{P}^n \) of sections \( \mathbf{s} = s_\lambda \in E_Y \), and, moreover, \( D_{\rho + 1}(\mathbf{s}) \mid D_\rho(\mathbf{s}) \) is the locus of points \( p \in \mathbb{P}^n \) such that there exists a unique \( \mathbf{s} \in \mathbb{P}E_Y \) that vanishes both at \( Y \) and at \( p \).

**Proof.** Recall that

\[
U_{\rho + 1} = D_{\rho + 1}(\mathbf{s}) \cap U = \{ x \in U \mid \text{rk} A_\mathbf{s}(x) \leq \rho \}
\]

\[
= \{ x \in U \mid A_\mathbf{s}(x) \cdot \vec{\lambda} = \vec{0}, \text{ for some } 0 \neq \vec{\lambda} = (\lambda_0, \ldots, \lambda_\rho)^t \in \mathbb{K}^{\rho + 1} \}
\]

\[
= \{ x \in U \mid \text{there exists } \vec{\lambda} \neq \vec{0} \in \mathbb{K}^{\rho + 1} \text{ such that } \delta_\lambda(x) = \sum_{i=0}^{\rho} \lambda_i \delta_i(x) = \vec{0} \}
\]

\[
= \{ x \in U \mid s_\lambda(x) = 0, \text{ for some } s_\lambda \in E_Y \},
\]
which proves the first statement.
For the second one, recall that \((D_{r+1}(s) \setminus D_r(s)) \cap U\) is the set of \(x \in U\) such that \(\text{rk} A_s(x) = \rho\), so that there exists a unique \(\bar{0} \neq \bar{\lambda}\) (modulo scalar multiplication) such that \(s_\lambda(x) = 0\) for \(s_\lambda = \sum_{i=0}^\rho \lambda_i s_i \in \mathbf{E}_Y\). \(\square\)

**Remark 2.2.** Under the conditions of Lemma 2.1:

1. We have \(D_{r+1}(s) \setminus D_r(s) \neq \emptyset\): Indeed, if \((D_{r+1}(s) \setminus D_r(s)) \cap U = \emptyset\) for every such \(U\), then the sections in \(s\) are linearly dependent in all \(\mathbb{P}^n\) and hence, they form no basis of \(\mathbf{E}_Y\), which is absurd.

2. It is easy to see that, for \(\tau = \rho + 1\), we have \(D_\tau(s) = D_\tau(s')\), for any other \(\mathbf{K}\)-basis \(s'\) of \(\mathbf{E}_Y\). This allows us to define \(D_\tau(Y)\) to be \(D_\tau(s)\), for some \(\mathbf{K}\)-basis \(s\) of \(\mathbf{E}_Y\), and

\[
C_Y = D_{\rho+1}(Y) \setminus D_\rho(Y).
\]

Hence, \(C_Y\) is nonempty for every \(Y \in \mathbb{N}_\omega\) and it follows from Lemma 2.1 that, for every \(Y^1 \subseteq Y \times \{p\} \in \mathbb{N}_\omega \times C_Y \subseteq S^{\omega+1}\mathbb{P}^n\), there exists a unique \([s] \in \mathbb{P}\mathbf{E}_{Y^1}\). It follows moreover that

\[
\dim C_Y = \dim D_{\rho+1}(Y), \text{ for every } Y \in \mathbb{N}_\omega.
\]

We have the following refinement of [2, II§4 Proposition 4.1]:

**Proposition 2.3.** Let \(n \geq 2\) and \(r \geq 2\) be integers such that

\[
eq 1 \equiv \rho \mod n, \text{ with } 1 \leq \rho \leq n - 1
\]

and let \(Y \in \mathbb{N}_\omega\). Then, \(D_{\rho+1}(Y)\) has the expected codimension \(n - \rho\) and hence it is a complete intersection. In consequence, it is not only (arithmetically) Cohen-Macaulay, but also equidimensional of dimension \(\rho\). In particular, \(C_Y\) is equidimensional of dimension \(\rho\).

**Proof.** Let \(s = \{s_0, \ldots, s_\rho\}\) be a \(\mathbf{K}\)-basis of \(\mathbf{E}_Y\). On the one hand, it follows from (2.6) that we may assume that \(\mu([s_i], p) = 1\), for every \(p \in Y\) and every \(i = 0, \ldots, \rho\). On the other hand, consider the matrix \(A_s(x)\) from (2.7), with \(x\) in some such \(U \subset \mathbb{P}^n\). For \(J = \{j_1 < \cdots < j_{\rho + 1}\}\), let

\[
A_s(x)^J = \begin{pmatrix}
  s_0^{j_1}(x) & \cdots & s_\rho^{j_1}(x) \\
  \vdots & \ddots & \vdots \\
  s_0^{j_{\rho + 1}}(x) & \cdots & s_\rho^{j_{\rho + 1}}(x)
\end{pmatrix}
\]

be a (maximal) minor of \(A_s(x)\) from (2.8). We have already seen in (2.9) that

\[
\text{codim} D_{\rho+1}(Y) \leq n - \rho.
\]

If \(\rho = n - 1\), then it is clear that \(D_n(Y)\) is a hypersurface, so we can assume that \(\rho < n - 1\): Assume that \(\text{codim} D_{\rho+1}(Y)\) is strictly smaller than \(n - \rho\), say, equal to \(n - \rho - 1\), then one of these (maximal) minors \(A_s(x)^J\) has determinant *identically* equal to zero and hence, at least one of its rows is linearly dependent to the others. This implies that, for every \(s_i \in s\), no \(p \in Y \cap U\) is an isolated singularity of \(s_i\), because \(\{s_1^1, \ldots, s_{\rho + 1}^n\} \subset \mathcal{O}_{\mathbb{P}^n, p}\) is not a regular sequence. This contradiction shows that \(\text{codim} D_{\rho+1}(Y) = n - \rho\). The Cohen-Macaulay and equidimensionality properties of \(D_{\rho+1}(Y)\) follow from [8] (Proposition 18.13 and Corollary 18.14, respectively). The last statement is clear from Remark 2.2. \(\square\)

**Proof of Theorem 1.3 (b).** In analogy with (2.3), let

\[
Z_{\omega+1} = \{(Y^1, [s]) \in S^{\omega+1}\mathbb{P}^n \times \mathbb{P}\mathbf{E} \mid Y^1 \subset ([s])_0 \subset S^{\omega+1}\mathbb{P}^n \times \mathbb{P}\mathbf{E},
\]
with restrictions $\Pi_1 : Z_{\omega+1} \rightarrow S^{\omega+1}\mathbb{P}^n$ and $\Pi_2 : Z_{\omega+1} \rightarrow \mathbb{PE}$. Consider

\[
\widetilde{N}_{\omega+1} = \{Y^1 = Y \times \{p\} \mid Y \in N_\omega \text{ and } p \in D_{\rho+1}(Y)\} \subset S^{\omega+1}\mathbb{P}^n,
\]

(2.10) $\widetilde{N}_{\omega+1}' = \{Y^1 = Y \times \{p\} \mid Y \in N_\omega \text{ and } p \in D_{\rho}(Y)\} \subset \widetilde{N}_{\omega+1}$, and

$M_{\omega+1} = \{Y^1 = Y \times \{p\} \mid Y \in N_\omega \text{ and } p \in C_Y\} \subset \widetilde{N}_{\omega+1}$.

Let

\[
\bar{Z}_{\omega+1} = \Pi_1^{-1}(\widetilde{N}_{\omega+1}) \subset Z_{\omega+1}
\]

and let $\bar{\pi}_1 : \bar{Z}_{\omega+1} \rightarrow \bar{N}_{\omega+1}$ and $\bar{\pi}_2 : \bar{Z}_{\omega+1} \rightarrow \mathbb{PE}$ be the restrictions to $\bar{Z}_{\omega+1}$ of the projections $\Pi_1$ and $\Pi_2$ above, respectively.

$\bar{N}_{\omega+1}$ is a nonempty quasiprojective subvariety, possibly reducible (for $D_{\rho+1}(Y)$ may have components), singular (for $D_{\rho+1}(Y)$ is singular along $D_{\rho}(Y)$), but equidimensional of dimension equal to $e - 1$.

We claim that, set-theoretically:

\[
\bar{\pi}_2(\bar{Z}_{\omega+1}) = \Pi_2(\bar{Z}_{\omega,0}) \supset V_\omega \neq \emptyset,
\]

and in consequence, $\bar{\pi}_2$ is dominant (because $V_\omega = \mathbb{PE}$).

It only remains to prove the equality in the claim and this goes as follows: $[s] \in \Pi_2(\bar{Z}_{\omega,0})$ if and only if $[s] = \Pi_2(Y, [s])$, for some $Y \in N_\omega$ and $Y \subset ([s])_0 \subset D_{\rho+1}(Y)$ by Lemma 2.1. In particular, any $q \in ([s])_0 \setminus Y$ lies in $D_{\rho+1}(Y)$ so that $[s] = \bar{\pi}_2(Y \times \{q\}, [s])$, with $Y^1 = Y \times \{q\} \in \bar{N}_{\omega+1}$.

The reciprocal inclusion is trivial.

We claim moreover that there exist

\[
[s] \in V_\omega \text{ such that } [s] = \bar{\pi}_2(Y \times \{p\}, [s]), \text{ with } p \in C_Y (Y \in N_\omega).
\]

Otherwise, for every $[s] \in V_\omega$, $[s] = \bar{\pi}_2(Y \times \{q\}, [s])$, for some $q \in D_{\rho}(Y)$ and the restriction $\bar{\pi}_2$ of $\bar{\pi}_2$ to $\bar{\pi}_2^{-1}(\bar{N}_{\omega+1}')$:

\[
\bar{Z}_{\omega+1} \supset \bar{\pi}_2^{-1}(\bar{N}_{\omega+1}') \xrightarrow{\bar{\pi}_1^{-1}} \mathbb{PE}
\]

is dominant. This is absurd, for $\dim \bar{\pi}_2^{-1}(\bar{N}_{\omega+1}') < e - 1$, by Remark 2.2, and (2.11) follows.

Finally, by the moment, we claim that

\[
\mu([s_0], q) = 1, \text{ for every } [s_0] \text{ and } q \in Y \times \{p\} \in M_{\omega+1} \text{ satisfying (2.11)}.
\]

It follows from Lemma 2.1 that $[s_0]$ is the unique foliation that vanishes at every

\[
q \in Y^1 = Y \times \{p\},
\]

so that $\{[s_0]\} = \mathbb{PE}_{Y^1} \subset \mathbb{PE}$ is zero-dimensional. By [10, Lemma 1.2],

\[
\{[s] \in \mathbb{PE}_{Y^1} \mid \mu([s], q) > 1, \text{ for some } q \in Y^1\}
\]

is a proper closed subset of $\mathbb{PE}_{Y^1}$, hence is empty, and the conclusion follows.

Now, let

\[
\bar{Z}_{\omega+1}^1 = \bar{\pi}_1^{-1}(M_{\omega+1}) \subset \bar{Z}_{\omega+1}
\]

(which is non-empty by (2.11)) and let $\bar{\Pi}_1 : \bar{Z}_{\omega+1} \rightarrow M_{\omega+1}$ and $\bar{\Pi}_2 : \bar{Z}_{\omega+1} \rightarrow \mathbb{PE}$ be the restrictions to $\bar{Z}_{\omega+1}$ of the projections $\Pi_1$ and $\Pi_2$.

The quasiprojective variety $M_{\omega+1}$ is non-empty, possibly reducible but equidimensional of dimension equal to $e - 1$, by Proposition 2.3. Moreover, $\bar{\Pi}_1$ is surjective and for every $Y^1 \in M_{\omega+1}$, the fibre $\bar{\Pi}_1^{-1}(Y^1)$ has dimension zero (it is a closed point $(Y^1, [s])$ because $[s]$ is unique, by
Lemma 2.1). This, together with [13, Theorem 1.26], shows that for every irreducible component $M_{ω+1}^c$ of $M_{ω+1}$,
\[ \tilde{Z}_{ω+1}^1 = \tilde{Π}_1^{-1}(M_{ω+1}^c) \subset \tilde{Z}_{ω+1}^1 \]
is irreducible and has dimension $e - 1$. It is hence a component of $\tilde{Z}_{ω+1}^1$.

Now consider a component $\tilde{Z}_{ω+1}^1$ containing a $(Y \times \{p\}, \{s\})$ satisfying (2.11) and let
\[ (2.13) \quad \tilde{Π}_2 : \tilde{Z}_{ω+1}^1 \rightarrow PE \]
be the restriction to $\tilde{Z}_{ω+1}^1$ of the map $\tilde{Π}_2$. As with part (a), the proof of Theorem 1.3 (b) follows if we prove that $\tilde{Π}_2$ is dominant, for, in this situation [11, Proposition 6.4.1] gives the existence of the Zariski-open set we are seeking for: $V_{ω+1} \subset \tilde{Π}_2^c(\tilde{Z}_{ω+1}^1)$, open and dense in $PE$, the closure of $\tilde{Π}_2^c(\tilde{Z}_{ω+1}^1)$.

We prove that $\tilde{Π}_2$ is dominant modifying the previous proof that $Π_2 : Z_{y,0} \rightarrow PE$ is dominant, this time letting $B = \tilde{Π}_2^c(\tilde{Z}_{ω+1}^1)$: If it were not, then we may assume that $\tilde{B} = C$ is an irreducible hypersurface and there exists a nonempty subset $V^\prime \subset B$ open and dense in $C$ such that $\dim (\tilde{Π}_2^c)^{-1}(\{s_0\}) = \dim \tilde{Z}_{ω+1}^1 - \dim C = 1$, for every $[s_0] \in V^\prime$. Since
\[ (2.14) \quad (\tilde{Π}_2^c)^{-1}(\{s_0\}) = \{(Y^1, [s_0]) | Y^1 \in M_{ω+1} \text{ and } Y^1 \subset ([s_0])_0\}, \]
the condition $\dim (\tilde{Π}_2^c)^{-1}(\{s_0\}) = 1$ implies that some $p \in Y^1$ is a non-isolated singularity of $[s_0]$, for every $[s_0] \in V^\prime$.

But on the other hand, these $[s_0]$ certainly do satisfy (2.11) for some $Y^1 = Y \times \{p\} \in M_{ω+1}$ and hence, they also must satisfy (2.12). This contradiction shows that (2.13) is dominant and the proof of Theorem 1.3 (b) has been completed.

\[ \square \]

3. Closing remarks

For $n = 2$ and $r \geq 2$, let $M_r = r(r + 5)/2$. It is easy to see that
\[ m(2, r - 1) = M_r - (t - 1), \quad \text{either if } r = 2t \text{ or } 2t + 1. \]
Recall form [7, Theorem 3.5] that for every non-degenerate foliation $[s]$ of degree $r$ in $P^2$, there exists a subscheme $Z \subset ([s])_0$ of degree $M_r$ which determines $[s]$ uniquely (although $K = \mathbb{C}$ in [7], the attentive reader will notice that the results therein hold for an algebraically closed ground field $K$).

For small values of $r$, we have the following values:

<table>
<thead>
<tr>
<th>$r$</th>
<th>$m(2, r - 1)$</th>
<th>$M_r$</th>
<th>$c_2(Θ_{P^2}(r - 1))$</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>7</td>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>3</td>
<td>12</td>
<td>12</td>
<td>13</td>
</tr>
<tr>
<td>4</td>
<td>17</td>
<td>18</td>
<td>21</td>
</tr>
<tr>
<td>5</td>
<td>24</td>
<td>25</td>
<td>31</td>
</tr>
<tr>
<td>6</td>
<td>31</td>
<td>33</td>
<td>43</td>
</tr>
<tr>
<td>7</td>
<td>40</td>
<td>42</td>
<td>57</td>
</tr>
</tbody>
</table>

We conclude that for a non-degenerate foliation $[s]$ of degree 2 in $P^2$ no proper subscheme of $([s])_0$ may uniquely determine $[s]$ and that every non-degenerate foliation $[s]$ of degree 3 in $P^2$ has a minimal subscheme which uniquely determines it.

At this point, we can moreover prove (see [12]) that for any such $Z \subset ([s])_0$, there exists a subscheme of degree $M_r - 1$ of $Z$ which still determines $[s]$ uniquely. The conclusion is that every
non-degenerate foliation \([s]\) of degrees 4 and 5 in \(\mathbb{P}^2\) has a minimal subscheme which uniquely determines it.

The question whether every non-degenerate foliation \([s]\) of degree \(r \geq 6\) in \(\mathbb{P}^2\) has a minimal subscheme which uniquely determines it remains open.
