9 ABSTRACT

10 Restoring the longitudinal connectivity of rivers is one of the main objectives of
11 environmental European directives and policies. Fish passes or fishways are one
12 of the most common actions for its restoration. Despite the great number of fish
13 passes constructed during the last two decades to comply with these policies,
14 few of them have been assessed and their suitability for fish movements is
15 unknown. There are different options to assess fish passes, but time and
16 economic costs frequently limit their application. Coarse fishway assessment
17 methods (CFAMs) are an easy, fast and economic alternative for this purpose.
18 This study aims to display the potential of CFAMs to evaluate a large number of
19 fishways, to show the actual status of fishways in an Iberian representative river
20 basin, and to diagnose their suitability and problems. For this, the Spanish Duero
21 River Authority promoted the assessment of 64 stepped fishways in the Duero
22 River basin (Spain) using the AEPS methodology. The results were analyzed
23 considering the four stages that a fish must overcome in a fishway (attraction,
24 entry, passage and exit), the fishway type and the construction period. Among
25 others, results show that 50 % of the assessed fishways allow the free movement
26 of fish. However, this percentage could have been greater applying an adequate

27 monitoring program for the fishway design and construction. Furthermore, the
28 diagnosis by stages of the AEPS methodology allowed to identify the attraction
29 and passage as the most problematic stages and also helped to define specific
30 retrofitting solutions for each fishway. The study concludes that the application of
31 CFAM during fishway design, construction and first operation stages can
32 increase their effectiveness and, thus, the number of fish passes that contribute
33 to the restoration of the longitudinal connectivity of rivers.

41 **1. INTRODUCTION**

42 Since the earliest human settlements, rivers have been sources of food, energy,
43 transport and protection. This has generated many alterations in freshwater
44 ecosystems together with many positive and negative environmental impacts all
45 over the world (Dudgeon et al., 2006). One of the most harmful impacts is the
46 rupture of river longitudinal connectivity by cross-sectional barriers (Nilsson et al.,
47 2005). Among other consequences, these obstacles (e.g. dams, weirs, etc.)
48 directly affect to fish fauna by hindering or preventing their natural movements to
49 find suitable habitats for their reproduction, feeding and/or refuge (Lucas et al.,
50 2001; Wofford et al., 2005). This has caused the reduction and the disappearance
51 of many fish populations worldwide (Hall et al., 2011; Porcher and Travade, 2002;
52 Doadrio et al., 2011).

53 One of the main objectives of environmental European directives and policies is
54 to enhance the longitudinal connectivity of rivers to improve and recover their
55 biodiversity [e.g. Habitats Directive and Water Framework Directive (WFD)]. This
56 has led to the accelerated adoption of actions to restore the fluvial connectivity.
57 These actions range from the removal of the in-stream barriers to the capture and
58 transport of fish. Nevertheless, the most common alternative is the construction
59 of fish passes (also named as fishways) (Clay, 1995; FAO/DVWK, 2002; M.
60 Larinier, 2002), being stepped fishways the most widespread solution around the
61 world (Noonan et al., 2012). A stepped fishway consists on a succession of cross-
62 walls in a sloped channel, connected by slots, notches and/or orifices, that divide
63 the total height of the obstacle (H) in smaller drops (ΔH) to ensure that the

64 hydraulic conditions inside are in the range of the physical capacities of fish fauna
65 and, thus, enable their passage (Fuentes-Pérez et al., 2017).

66 However, inadequate designs or negligent constructions can lead to the
67 inefficiency of fish passes. Thus, building a fishway does not guarantee that fish
68 fauna can overcome an obstacle (Castro-Santos et al., 2009; Roscoe and Hinch,
69 2010) and their assessment becomes vital to ensure that they really help to the
70 restoration of river connectivity as well as to identify possible operating problems.
71 Nowadays, a small number of fishways has been assessed worldwide, obtaining
72 despair and in many cases negative results (Bunt et al., 2016, 2012).

73 The methods for fishway assessment can be classified in two major groups:
74 biological and hydraulic (Sanz-Ronda et al., 2013). Biological methods study the
75 fish that are using a fishway in order to assess its performance. They can be (1)
76 qualitative studies, which assess the effectiveness, determining if a fishway is
77 able or not to allow the fish passage, generally by visual inspection, video
78 recording, samplings, traps, etc.; and (2) quantitative studies, which assess the
79 efficiency, calculating the proportion of fish that locate, entry and overcome a
80 fishway (Bunt et al., 2012; Castro-Santos and Haro, 2010; Larinier, 2001),
81 generally by means of passive integrated transponders (PIT), acoustic or radio
82 telemetry (King et al., 2016; Roscoe and Hinch, 2010).

83 On the other hand, hydraulic methods compare geometrical and hydraulic
84 characteristics of the fishways with the physical capacities of fish (e.g. swimming
85 or jumping capabilities, turbulence tolerance, etc.), in order to assess the
86 effectiveness of the fish pass via qualitative indicators (Barry et al., 2018; Baudoin
87 et al., 2015). These procedures are usually named as coarse fishways

88 assessment methods (CFAM) and they are very practical because of their fast,
89 simple and inexpensive application (*i.e.* Armstrong et al. 2004; Solà et al. 2011;
90 Towler et al. 2013). There are some general experiences (CHE et al., 2011;
91 Santos et al., 2012) and several standardized protocols of this type of hydraulic
92 assessments: SNIFFER (2010), ICF (Solà et al., 2011), ICE (Baudoin et al., 2015)
93 or AEPS (CHD, 2016). SNIFFER and ICF compare values of water level
94 differences, depths and/or velocities inside the fishway with the fish ability to
95 overcome certain thresholds, complemented by expert opinions. ICE and AEPS,
96 besides the above, also include physical characteristics of the fish passes (e.g.
97 pool dimensions, power dissipation, etc.), and they are conceptually objective. In
98 the specific case of AEPS, besides the fish passage, it also considers the
99 attraction, entry and exit from the fishway. Furthermore, it takes into account
100 some outcomes and conclusions of several previous biological assessments
101 (Bravo-Córdoba et al., 2018b; Sanz-Ronda et al., 2019, 2016) to increase
102 confidence in the estimation of effectiveness.

103 Despite biological assessment methods provide richer information, their
104 application is more expensive than hydraulic methods as they require more time
105 together with specialized equipment and users (Barry et al., 2018). Therefore,
106 hydraulic based methods as CFAM are more useful to carry out large scale
107 fishway assessments. In addition, CFAM can also be used to detect fishway
108 potential problems and to provide specific solutions for its retrofitting.

109 In this paper, the use of CFAMs for assessing fish passes and identifying their
110 problematic aspects is analyzed. For this, the AEPS methodology is applied to
111 64 stepped fishways constructed from the mid-1990s to 2019 in the Duero River

112 basin (Spain). This work aims to (1) highlight the usefulness of CFAM methods
113 for assessing the effectiveness of fishways, and as tool for detecting errors and
114 possible retrofitting actions, (2) show the actual status of the fishways in the
115 Duero River basin, and (3) identify their main potential problems. In addition, the
116 analysis revealed interesting information about evolution of fishways over the last
117 years, their main problems, and the possible influence of recent regulations in
118 their construction. This paper provides a clear example to managers, engineers
119 and biologists on the usage of CFAMs to assess and improve the existent and
120 future fishways and to decide how to prioritize efforts during river restoration.

121

122 **2. MATERIAL AND METHODS**

123 To achieve the proposed objectives, the AEPS methodology has been applied to
124 asses 64 step-pool fishways. Herein this section, we start by presenting briefly
125 the AEPS methodology (section 2.1) followed by a description of the study cases
126 (section 2.2), and data collection procedure (section 2.3). Finally, we present the
127 data treatment and statistical analyses (section 2.4) in order to obtain
128 comprehensive and statistically relevant results about the ascent stages through
129 fishways (attraction, entry, passage and exit), the type of fishway, its physical and
130 hydraulic parameters, and its construction period.

131

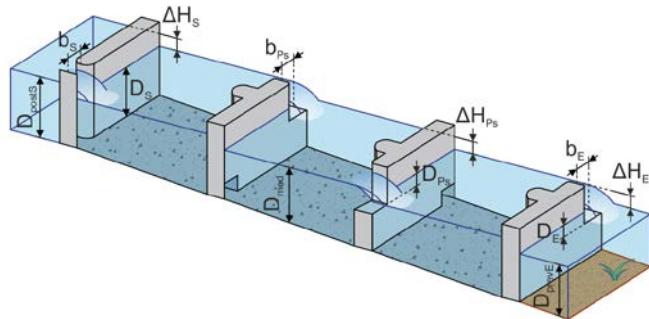

132 **2.1. DESCRIPTION OF THE AEPS METHODOLOGY**

133 The AEPS methodology (CHD, 2016) is a CFAM for stepped fishways evaluation
134 developed by the Spanish Duero River Authority (Confederación Hidrográfica del
135 Duero-CHD) in 2016 (www.gea-ecohidraulica.org/AEPSv1.pdf). The acronym

136 AEPS derives from the Spanish names of the four stages that fish must overcome
 137 in their ascent through a fish pass (Castro-Santos et al., 2009): attraction, entry,
 138 passage and exit. These stages are assessed studying twenty variables of easy
 139 measurement (table 1 and figure 1).

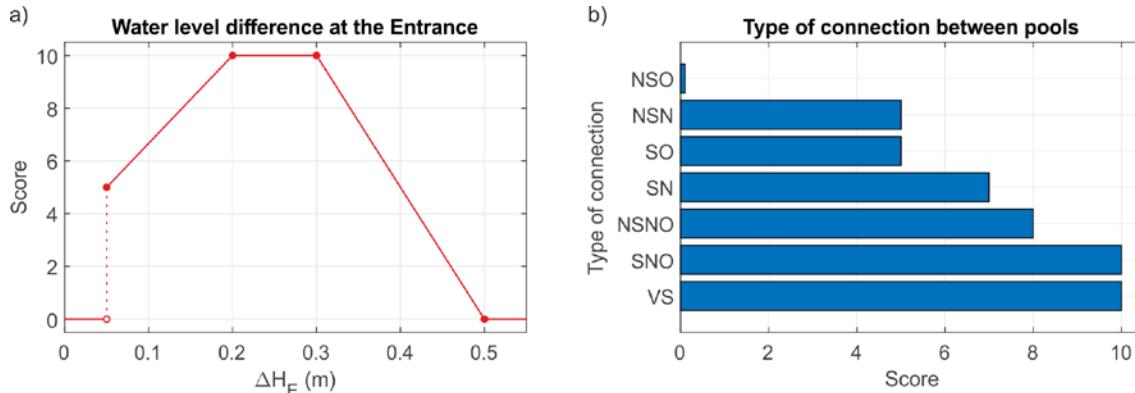

140 Table 1. Variables included in the assessment of the four stages that the AEPS methodology considers (see
 141 Figure 1).

| STAGE | VARIABLES (ABBREVIATION) |
|--|--|
| Attraction | Relative flow of attraction ($Q_{attraction}$) |
| | Location of the fish entrance (L_E) |
| Entry | Water level difference at the entrance (ΔH_E) |
| | Water depth at the entrance (D_E) |
| | Width of the entrance (b_E) |
| | Water depth before the entrance (D_{prevE}) |
| Passage | Orientation of the entrance respect to the river (Ort_E) |
| | Type of entrance (T_E) |
| | Water level difference between pools (ΔH_{Ps}) |
| | Volumetric power dissipation (N) |
| Exit | Mean water depth in the pool (D_{med}) |
| | Water depth between pools (D_{Ps}) |
| | Width between pools (b_{Ps}) |
| | Type of connection between pools (T_{Ps}) |
| | Water level difference at the exit (ΔH_s) |
| | Water depth at the exit (D_s) |
| | Width of the exit (b_s) |
| | Water depth after the exit (D_{postS}) |
| Orientation of the exit respect to the river (Ort_s) | |
| Type of exit (T_s) | |

144 Figure 1. Variables to be measured in a fishway according to AEPS methodology (ΔH – water level
 145 difference; D – water depth; b – width for fish passage; D_{prevE} – water depth before the entrance; D_{med} –
 146 mean water depth in the pool; D_{postS} – water depth after the exit; E – entry; Ps – passage; s – exit) (see table
 147 1).

149 Each variable is graphically or categorically scored from 0 (very unsuitable for the
 150 ascent of the target fish fauna) to 10 (very suitable) (figure 2). The graphical and
 151 categorical scoring systems of AEPS are based on the recommendations of
 152 specialized literature, laboratory studies and field experiences. The AEPS
 153 methodology is focused on the main potamodromous fish species of the Duero
 154 River basin: the brown trout (*Salmo trutta*, Linnaeus 1758) and two rheophilic
 155 cyprinids: the Iberian barbel (*Luciobarbus bocagei*, Steindachner 1864) and the
 156 northern straight-mouth nase (*Pseudochondrostoma duriense*, Coelho 1985),
 157 because they are the most relevant species in terms of biomass and distribution
 158 in the basin. However, using the same scores, it can be applied to other species
 159 with similar capacities and requirements, or it can be adapted to other species
 160 modifying the scoring values.

161

162 Figure 2. Scoring systems for two variables considered in the AEPS methodology: (a) graphical scoring
 163 system for the water level difference at the entrance (based on: Armstrong et al., 2004; Larinier, 2002b), (b)
 164 and categorical scoring table for the type of connection between pools (based on: Baudoin et al., 2015; Clay,
 165 1995; FAO and DVWK, 2002) (NSO – non-submerged orifices; NSN – non-submerged notches; SO –
 166 submerged orifices; SN – submerged notches; NSNO – non-submerged notches and orifices; SNO –
 167 submerged notches with orifices; VS – vertical slots) (see the original reference (CHD, 2016) for more
 168 information).

169

170 The score of each stage (attraction, entry, passage and exit) is obtained by
 171 geometric means of the scored variables (eq. 1 to eq. 4, see notation section for
 172 further clarification). The geometric means allow to classify a whole stage as
 173 unsuitable if at least one of its variables is also unsuitable.

$$\text{Attraction} = (Q_{\text{attraction}} \cdot L_E)^{1/2} \quad (\text{Eq. 1})$$

$$\text{Entry} = (\Delta H_E \cdot D_E \cdot b_E \cdot D_{\text{prev}E} \cdot \text{Ort}_E \cdot T_E)^{1/6} \quad (\text{Eq. 2})$$

$$\text{Passage} = (\Delta H_{Ps} \cdot N_{Ps} \cdot t_{\text{med}} \cdot D_{Ps} \cdot b_{Ps} \cdot T_{Ps})^{1/6} \quad (\text{Eq. 3})$$

$$\text{Exit} = (\Delta H_S \cdot D_S \cdot b_S \cdot D_{\text{post}S} \cdot \text{Ort}_S \cdot T_S)^{1/6} \quad (\text{Eq. 4})$$

174

175 The methodology classifies the suitability of each stage, as well as the suitability
 176 of each variable, as: Highly Suitable or *HS* ($8 < \text{Score} \leq 10$), Suitable or *S* ($6 <$
 177 $\text{Score} \leq 8$), Unsuitable or *U* ($4 < \text{Score} \leq 6$), and Highly Unsuitable or *HU* ($0 \leq$

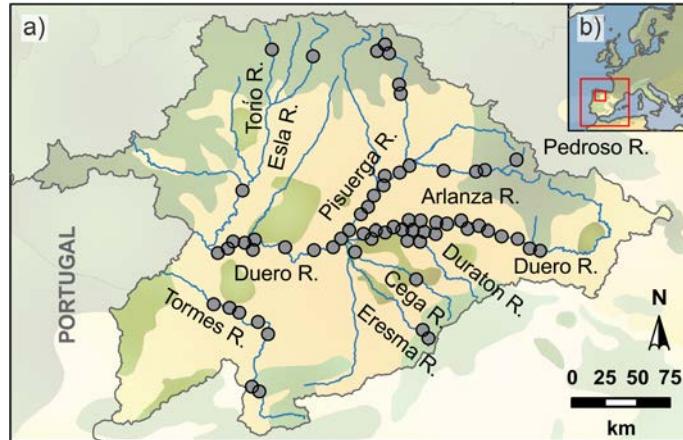

178 Score \leq 4). This discretization of the scores allows to define potential problems
179 of the fishway and their specific solutions. Finally, the lowest value of the four
180 stages is considered as the overall score for the whole fishway.

181

182 2.2. STUDY CASES

183 All the studied fishways are located in the Duero River basin, the largest basin of
184 the Iberian Peninsula. It is a transboundary system of 97,290 km² shared by
185 Portugal (19 %) and Spain (81 %) (CHD, 2020) (figure 3). Most of the Spanish
186 side is under Mediterranean-continental climate, with a mean annual precipitation
187 of 612 mm, and a contribution to rivers and underground systems of 15,000 hm³
188 per year (CHD, 2020).

189 The AEPS methodology was applied to 64 stepped fishways associated to
190 hydropower plants located in the Spanish side of the Duero River basin (figure
191 3). Priority for the evaluation was given to those fishways located in sensitive
192 zones, in the mainstem of the Spanish side of the Duero River and the lower parts
193 of its tributaries. However, these fishways are about the 50 % of the existing
194 stepped fish passes in the whole basin and more than 75 % of those built since
195 the implementation of the WFD in 2000 (CHD, 2019a).

196

197 Figure 3. Study area. (a) Location of the assessed fishways in the Spanish side of the Duero River basin (R.
 198 – river), (b) northwest of the Iberian Peninsula, southern Europe.

199

200 2.3. DATA COLLECTION

201 Data collection was carried out when the river flow of each study site (obtained
 202 from SAIH real time gauging stations (CHD, 2019b)) was similar to the one during
 203 the reproductive migration of the target species (public database of CEDEX
 204 (CEDEX, 2019)). The northern straight-mouth nase and the Iberian barbel usually
 205 perform reproductive migrations from April to June, while the brown trout from
 206 November to January in the Iberian Peninsula (Doadrio et al., 2011; García-Vega
 207 et al., 2017; Kottelat and Freyhof, 2007).

208 Water levels and height differences in the fishways were measured with a
 209 topographic total station Leica TC307 (± 1 cm). Geometrical characteristics of the
 210 fishways were measured with metal rulers to the same precision level. Based on
 211 the previous information, the discharges through the fishways were estimated
 212 using the formulation for stepped fishways proposed by Fuentes-Pérez et al.
 213 (2017).

214

215 2.4. DATA TREATMENT

216 The collected information in each fishway was processed following the AEPS
217 methodology, obtaining the scores for the twenty variables (table 1), the four
218 stages (eq. 1-4) and the overall score and suitability category (*HS*, *S*, *U* or *HU*)
219 for each assessed fishways. Furthermore, the suitability categories of AEPS
220 methodology were gathered in two final groups of effectiveness: favorable (*HS*
221 and *S*) and unfavorable to fish movements (*HU* and *U*)

222 The evaluated stepped fishways were classified in five groups according to their
223 connections between cross-walls: vertical slots (*VS*), submerged notches (*SM*),
224 submerged notches with orifices (*SNO*), non-submerged notches (*NSM*) and non-
225 submerged notches with orifices (*NSNO*) fishways. To study the relation among
226 variables, stages and the type of stepped fishways, linear mixed models of
227 analysis of variance were used. Mixed models relate a response or dependent
228 variable (type of stepped fishways) with one or more explanatory or independent
229 variables (stages and variables), considering the possible existence of correlated
230 observations or with heterogeneous variability linked to the presence of random
231 factors.

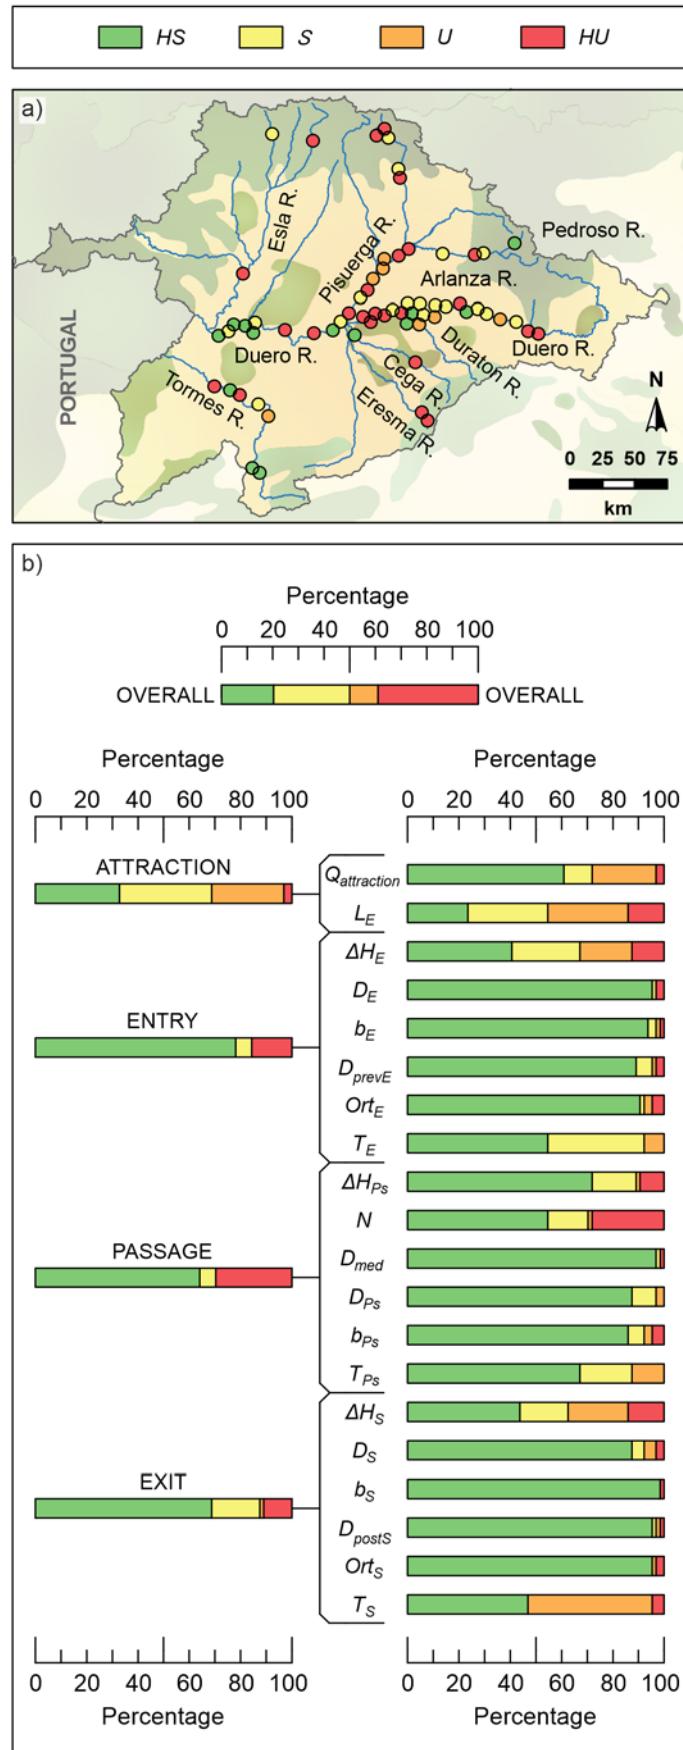

232 To identify which were the most problematic variables and/or stages, a frequency
233 analysis of the suitability categories by variable, stage and the overall
234 performance of the evaluated fishways was performed, by type of stepped
235 fishway and construction period. For this purpose, two periods were considered,
236 from the mid-1990s to 2009 and from 2010 to 2019. The division by construction
237 period was considered to assess the possible impact of the implementation of the

238 WFD is the Duero basin. The Chi-squared test was used to evaluate if there were
239 significant differences in effectiveness between both construction periods.
240 All the statistical analyses were performed using SAS® and Statgraphics
241 Centurion.

242

243 **3. RESULTS**

244 Half of the assessed fishways showed a favorable effectiveness (29.7 % *S* and
245 20.3 % *HS*), meanwhile the other half showed problems related to the design,
246 construction or operation (10.9 % *U* and 39.1 % *HU*) (figures 4a and 4b) (see
247 appendix A). Most of the problems were identified at the Attraction and Passage
248 stages, where almost the third part of the fishways were classified as unfavorable
249 (figure 4b). The mean score of the Attraction was significantly lower than the
250 scores of the rest of the stages (7.05 ± 0.37 ; $p < 0.05$; table 2).

252 Figure 4. Effectiveness of the studied fishways according to the AEPS methodology: (a) location of the
253 studied fishways in the Duero River basin and their overall classification (R. – river), (b) percentage of
254 fishways in each suitability category (*HS* – Highly Suitable; *S* – Suitable; *U* – Unsuitable; *HU* – Highly
255 Unsuitable), in total (overall) and by stages and variables (see table 1 for abbreviation description).

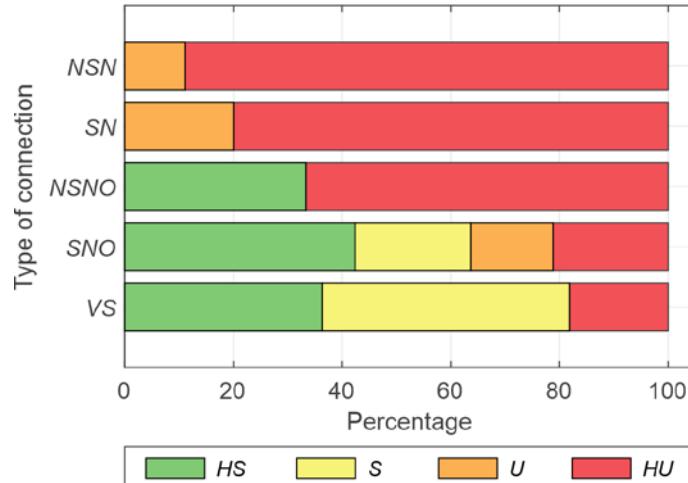

256

257 Attraction problems were mainly caused by an inadequate location of the fish
258 entrance (L_E) (45.3 %), rather than by an inefficient attraction flow ($Q_{attraction}$) (28.1
259 %) (figure 4b). These inefficient flows were caused by fishway discharges that,
260 although they ranged from 150 L/s to 500 L/s and in general were about 300 L/s,
261 they were lower than 3.0 % of the usual river flow during the migration season.

262 For the Passage stage, an excessive volumetric power dissipation (N) was the
263 main source of low suitability. This variable is calculated from others such as ΔH_{Ps}
264 and D_{med} (Towler et al., 2015), which were favourable in a greater proportion of
265 cases (89.1 % and 98.4 %, respectively), than N (70.3 %) (figure 4b).

266 In the Entry and Exit stages, the variables lower scored were those related to a
267 poor adjustment between the water level in the river and the water level in the
268 fish entrance or exit pools (ΔH_E and ΔH_S). The Exit stage was also very
269 conditioned by the type of connection between the upper pool and the river (T_S),
270 where in many cases were free overfalls (figure 4b).

271 According to the type of stepped fishway, VS were the most effective, with 81.8
272 % classified as favorable and displaying the greatest score (9.39 ± 0.17 ; $p < 0.05$).
273 Secondly, SNO showed a score of 8.89 ± 0.18 and 63.6 % of favorable cases,
274 meanwhile NSNO and NSN types obtained the lowest scores (figure 5 and table
275 2).

276

277 Figure 5. Studied fishways in each suitability category by type of stepped fishway according to AEPS
 278 methodology (HS – Highly Suitable; S – Suitable; U – Unsuitable; HU – Highly Unsuitable; NSN – non-
 279 submerged notches; SN – submerged notches; NSNO – non-submerged notches and orifices; SNO –
 280 submerged notches with orifices; VS – vertical slots).

281

282 Table 2. Linear mixed model outcomes: mean score and standard error for each type of stepped fishway by
 283 stage and overall. Different uppercase or lowercase letters over the mean values show significant differences
 284 between stages or types, respectively ($\alpha = 0.05$) (VS – vertical slot fishways; SN – submerged notches;
 285 SNO – submerged notches with orifices; NSN – non-submerged notches; NSNO – non-submerged notches
 286 and orifices; n – number of fishways).

| TYPE | <i>n</i> | STAGE | | | | ALL STAGES |
|------|----------|----------------------------|-----------------------------|----------------------------|-----------------------------|--------------------------|
| | | ATTRACTION | ENTRY | PASSAGE | EXIT | |
| VS | 11 | C a (8.21 ± 0.65) | B a (9.46 ± 0.30) | A a (9.91 ± 0.12) | B a (9.17 ± 0.39) | a (9.39 ± 0.17) |
| SN | 5 | C c (5.08 ± 1.47) | A bc (8.93 ± 0.26) | B c (7.28 ± 0.65) | B bc (8.49 ± 0.53) | c (7.92 ± 0.31) |
| SNO | 33 | B b (7.38 ± 0.46) | A ab (9.05 ± 0.35) | A b (9.15 ± 0.37) | A ab (8.98 ± 0.27) | b (8.89 ± 0.18) |
| NSN | 9 | C c (5.83 ± 0.44) | A d (7.84 ± 0.97) | B c (6.59 ± 0.52) | A bc (8.24 ± 0.63) | d (7.38 ± 0.39) |

| ALL TYPES | 64 | B (7.05 ± 0.37) | A (8.83 ± 0.25) | A (8.61 ± 0.24) | A (8.73 ± 0.29) | |

287

288 Most of the evaluated fishways (62.5 %) were constructed or modified during
 289 2010-2019. In addition, there was a variation in the election of type of stepped
 290 fishway over time (table 3a). During the period from the mid-1990s to 2009, the
 291 most constructed type was NSN (37.5 %) whereas during 2010-2019 it was SNO
 292 (67.5 %) (table 3a). NSN and SN fishways were exclusively constructed during
 293 the first period, whereas VS in the second one. The effectiveness of all assessed
 294 stages increased significantly in the last period ($p < 0.05$; table 3b). In general
 295 terms, fishways constructed from 2010 had a significantly greater effectiveness
 296 than those built before 2010 (16.7 % vs. 70 % of favorable cases; $p < 0.05$) (figure
 297 3b).

298 Table 3. Changes over time of effectiveness (favorable – fishways classified as *HS* and *S*; unfavorable –
 299 fishways classified as *HU* and *U*) by (a) type of stepped fishways (*VS* – vertical slots; *SN* – submerged
 300 notches; *SNO* – submerged notches with orifices; *NSN* – non-submerged notches; *NSNO* – non-submerged
 301 notches and orifices) and (b) stages according to AEPS methodology (*n* – number of fishways).

302

303 4. DISCUSSION

304 Since the application of the European policies in the last two decades, a large
 305 number of fish passes have been constructed in European rivers (Barry et al.,
 306 2018). Therefore, it is essential to find methods to assess the efficiency of these
 307 devices in a reliable, fast and economical way. The application of the AEPS
 308 methodology, a hydraulic based CFAM, has allowed to describe the individual
 309 and global status of a large number of fish passes in a wide geographic area, and
 310 to detect fish passes with operational problems, with a lower investment and a
 311 faster and easier application than biological assessment methods. In general, for

312 biological efficiency studies, a minimum of 3 months (usual period of active
313 migration) is required to obtain reliable data, whereas CFAM, as AEPS, can be
314 applied in less than one day per fishway.

315 In this study, the usefulness of hydraulic based methods (AEPS methodology) is
316 demonstrated by assessing 64 stepped fishways in the Duero River basin. The
317 evaluation of fishway effectiveness by means of suitability scores and categories
318 provides a tool to prioritize actions and to distribute the resources for river
319 restoration and management. Likewise, the discretization of the scores by ascent
320 stages (attraction, entry, passage and exit) allows to diagnose possible problems
321 in each fish pass and to propose specific solutions for their retrofitting.

322

323 4.1. GLOBAL STATUS

324 Regarding the global status of the studied fishways, results show that 50 % of
325 assessed fishways are potentially suitable to allow the movements of main fish
326 species of the Duero River basin. This percentage rises to 70.3 % if only Passage
327 stage is considered. Close results were obtained in other Iberian regions, as
328 Catalonia 55 % (Ordeix et al., 2011; Solà et al., 2011) and Portugal 49 % (Santos
329 et al., 2012). In contrast, in a study developed in the Ebro River basin (one of the
330 largest rivers in Iberia), where 131 fish passes were evaluated, only 17.8 %
331 showed favorable results (CHE et al., 2011). The construction year (before 2011)
332 of the fishways included in that study may explain the observed differences. Our
333 results show that fishways constructed before 2010 displayed lower scores
334 (higher unsuitability) than fishways constructed after this year. This could be
335 explained by several reasons: (1) an increase in the knowledge of fishway design

336 (e.g. Fuentes-Pérez et al., 2017; Quaresma et al., 2018), (2) a better fit between
337 physical capabilities of fish and designs (e.g. Romão et al. 2012; Sanz-Ronda et
338 al. 2015), (3) a consolidation of the European guidelines (e.g. FAO/DWK 2002;
339 Larinier 2002b) and (4) a greater concern of Water River Authorities which control
340 and regulate more severely the construction process (Sanz-Ronda et al., 2013).
341 The study also shows an evolution over time toward streaming connections such
342 as VS and SNO, together with an increase of the scores, which seems to indicate
343 a better performance of these type of fishways. During last years, specialized
344 literature has pointed out that streaming connections are preferable than plunging
345 ones as they usually demand less effort for fish and do not require jumping
346 between pools; consequently they seem to be more suitable for rivers with fish
347 with wide morpho-ecological traits (Branco et al., 2013; Sanz-Ronda et al., 2016;
348 Silva et al., 2009). Furthermore, VS and SNO fishways have demonstrated good
349 performance for the passage of Iberian cyprinids as well as brown trout (Bravo-
350 Córdoba et al., 2018a; Sanz-Ronda et al., 2016, 2019). In addition, VS and SNO
351 present better self-regulation of the hydraulic variables than other fishway types,
352 which compensate possible construction errors and water level oscillations
353 (Fuentes-Pérez et al., 2016, 2014). Therefore, it seems that VS and SNO are the
354 preferable options for new constructions or retrofitting old ones.
355 Some of the studied SN fishways were working close to plunging regimens, that
356 is to say, with a low submergence in the notch (< 10 cm). One of the reason could
357 be that despite they were designed to operate in streaming regimens, i.e. as NSN,
358 the river dynamics or the lack of discharge management through the structures
359 favoured an operation in plugging regimen, i.e. as SN. Due to the multiple benefits

360 of streaming regimens (Branco et al., 2013; Sanz-Ronda et al., 2015a; Silva et
361 al., 2009) the operation under plugging regimens is penalized by AEPS.

362

363 4.2. DIAGNOSIS OF THE STUDIED FISHWAYS

364 The most frequent causes of fish pass failure include the lack of attraction flow,
365 inadequate location of the entrance, absence of maintenance and inadequate
366 hydraulic conditions (e.g. flow patterns, velocities or turbulence) inside the
367 fishway for the target species (FAO/DVWK, 2002; Larinier, 2001; Silva et al.,
368 2018; Williams et al., 2012). In this study, Attraction and Passage were the two
369 stages with the lowest scores. For Attraction stage, the location of the fish
370 entrance is essential. The optimal location is as close as possible to the most
371 upstream part of the barrier, adjacent to its base and/or to the exit of the turbines
372 in case of a powerhouse (M Larinier, 2002; Williams et al., 2012). Furthermore,
373 an attraction flow near the fish entrance is desirable to create a detectable flow
374 pattern not masked by other flows (Burnett et al., 2017; FAO/DVWK, 2002; M.
375 Larinier, 2002). 45.3 % of the studied fishways had an incorrect fish entrance
376 location and 28.1 % lacked an appropriate attraction flow in their surroundings. A
377 large number of works (e.g. Bunt et al., 2012; Larinier et al. 2005; Williams et al.
378 2012) identify these two variables as the main cause of inadequate operation of
379 the fishways. Once these problems have been identified, it is possible to
380 implement specific solutions for each case. For example, Bunt (2001) showed a
381 positive effect of approaching the fish entrance to the spillways.

382 Regarding the Passage, results show that it was negatively influenced by both
383 high water drops between pools (ΔH_{Ps} , in 10.9 % of the fishways) and small size

384 of the pools. This caused an excessive volumetric power dissipation within pools
385 (N , in the 29.7 % of the fishways). N is directly related to turbulence levels inside
386 the pools, which can disorient the fish (Clay, 1995; M. Larinier, 2002) and
387 increase the cost of swimming performance (Enders et al., 2005). Likewise, ΔH
388 is related to the water velocity and, when it exceeds fish swimming or jumping
389 capacities, the fish cannot pass the notches or slots (M. Larinier, 2002; Sanz-
390 Ronda et al., 2016). The correction of these deficiencies is usually challenging,
391 and some alternatives can be, for instance, the increase of the water volume in
392 the pool (by increasing the sill elevation in the notches, and thus, the water depth
393 in the pool) or the addition of extra pools and cross-walls in order to share the
394 excessive drops among them. If the failure is localized in a specific pool, this can
395 be retrofitted by modifying the successive cross-walls (Fuentes-Pérez et al.,
396 2016).

397 The water drop is usually a conflictive variable also in the Entry and Exit stages.
398 Despite the overall better results of these two stages (favorable > 80 %), in both
399 cases ΔH was the variable with the lowest score. Failures in this variable are
400 usually linked to (1) not considering the water level oscillations related to changes
401 in river discharge during the migration season in the design and operation of the
402 fishway, (2) a wrong on-site layout during the construction process or (3) the
403 modification of the river control sections during the construction. Although high
404 water level differences or plunging flows at the entrance can be related to a better
405 attraction (Williams et al., 2012), they can also exceed the swimming and/or
406 jumping capacities of fish (Ruiz-Legazpi et al., 2018; Sanz-Ronda et al., 2015b).
407 Likewise, small differences in water levels or excessive submergence can reduce

408 the velocity and turbulence at the entrance, affecting negatively to Attraction.
409 Larinier (2002b) recommends a minimum velocity of 1 m/s and a maximum of 2.4
410 m/s at the entrance. Excessive water level differences at the fish entrance can be
411 solved, for example, by installing a set of pre-barrages; meanwhile, the small
412 water drops can be corrected by increasing the sill elevation of the most
413 downstream notch or slot (Fuentes-Pérez et al., 2016).

414

415 4.3. OTHER CONSIDERATIONS

416 In general, the overall passage problems identified in this study can have two
417 main origins: (1) not considering the recommended criteria for fishway design or
418 (2) unsupervised modifications during the construction with respect to the original
419 project. Although the former is difficult to solve if there is not a project control
420 agent with advanced knowledge in the fishway design field, the latter could be
421 avoided with an adequate in-site inspection during the construction process
422 (Mallen-Cooper and Brand, 2007; Sanz-Ronda et al., 2013). An inspection based
423 on hydraulic evaluation methods (e.g. AEPS), after construction and prior to the
424 machinery retreat, could have solved the possible deficiencies, increasing the
425 percentage of favorably scored fishways.

426 In addition, the inspection process also allowed the identification of maintenance
427 problems (also considered in the AEPS methodology (CHD, 2016)). The 32.8 %
428 of the studied fishways presented problems due to obstructions (debris,
429 branches, leaves and other drifts). The fishways were cleaned before measuring
430 the variables needed for the application of the methodology. In absence of this
431 previous cleaning phase, the final scores could had been lower as these

432 obstructions may modify the hydraulics inside the fishway. Therefore, although
433 the first action to restore the longitudinal connectivity of a river stretch is the
434 fishway construction and its evaluation, the second one is the implementation of
435 a maintenance schedule adapted to the river dynamics in order to ensure its
436 adequate operation. Lastly, the final action is the application of a periodical and
437 effective control plan by the water authorities.

438

439 **5. SUMMARY AND CONCLUSIONS**

440 This paper analyses the functionality of AEPS as a coarse fishway assessment
441 method. The application of CFAM or hydraulic methods is in general a faster, less
442 expensive and simpler option than biological assessment methods, mainly due
443 to the nature of the variables to measure and the necessary tools for their
444 application. However, the uncertainties in these methods are greater than in
445 biological assessments due to the absence of fish monitoring. The easy and
446 simple application of the AEPS methodology has made possible to assess a large
447 number of fishways in a wide geographic area. Its application has also
448 demonstrated the need of an assessment after construction of any fishway, as
449 most of the assessed structures require retrofitting actions to ensure their
450 adequate operation.

451 The application of AEPS showed that 50 % of assessed fishways are potentially
452 suitable for fish movements and that VS and SNO fishway types were the most
453 effective ones. The research also revealed that fishway design improved their
454 effectiveness over time, probably due to an increase of knowledge of native fish
455 species and the consolidation of European regulations.

456 Attraction and Passage were the two stages with lower suitability scores. Most
457 relevant failures for the attraction were a poor location of the device and low
458 attraction flows, whereas for the passage, they were high water drops between
459 pools and small size of the pools. Fishways design and construction processes
460 were identified as the key causes of those defects, thus the control during these
461 processes have to be guaranteed, together with periodical inspections to ensure
462 a correct maintenance.

463 CFAMs seems a valid tool to handle the assessment of all the constructed
464 fishways. However, further research is necessary. Specifically, it is necessary the
465 improvement of CFAMs through their direct comparison with results from
466 biological methods, to relate them to biological efficiencies, and to incorporate
467 other fish species as well as other types of fish passes. Until then, we can
468 conclude that AEPS methodology and CFAMs in general, provide a systematic
469 tool to managers, engineers and biologist to identify and solve problems and
470 correct deviations by its application during design, construction and operation
471 phases of the existent and future fish passes.

472

473 **ACKNOWLEDGEMENTS**

474 This research was promoted and financed by the Spanish Duero River Authority
475 (Confederación Hidrográfica del Duero). Authors specially thank the collaboration
476 of the following members of the Agency: Arturo Prieto Blanco, Ignacio Rodríguez
477 Muñoz, José María Rubio Polo, Juan Carlos Bernabé de la Iglesia and Urbano
478 Sanz Cantalejo. Jorge Valbuena-Castro's contribution was initially financed by
479 Confederación Hidrográfica del Duero and afterwards by a public Ph.D. grant

480 from Junta de Castilla y León and European Social Fund PIF-2017. Juan
481 Francisco Fuentes-Pérez's and Francisco Javier Bravo Córdoba's contributions
482 were partly financed by Torres Quevedo grants PTQ2018-010162 and PTQ-16-
483 08494, respectively. Ana García-Vega's contribution was financed by a Ph.D.
484 grant from the University of Valladolid PIF-UVa 2017. Authors would like to thank
485 Valentín Pando Fernández for his statistical assistance, and Beatriz Baselga
486 Cervera and Irene Calderón Pastor for the revision of this paper.

487

488 **Notation**

489 The following symbols and abbreviations are used in this paper:

490 ΔH = water level difference or drop (m)

491 ΔH_E = water level difference at the entrance (m)

492 ΔH_{Ps} = water level difference between pools (m)

493 ΔH_s = water level difference at the exit (m)

494 b_E = width of the entrance (m)

495 b_{Ps} = width between pools (m)

496 b_s = width of the exit (m)

497 CFAM= coarse fishway assessment method

498 D_E = water depth at the entrance (m)

499 D_{med} = mean water depth in the pool (m)

500 D_{postS} = water depth after the exit (m)

501 D_{prevE} = water depth before the entrance (m)

502 D_{Ps} = water depth between pools (m)

503 D_s = water depth at the exit (m)

| | | | |
|-----|------------------|---|--|
| 504 | H | = | total height of an obstacle (m) |
| 505 | HS | = | highly suitable |
| 506 | HU | = | highly unsuitable |
| 507 | L_E | = | location of the fish entrance |
| 508 | n | = | number of fishways |
| 509 | N | = | volumetric power dissipation (W/m^3) |
| 510 | NSN | = | non-submerged notch with orifice fishway |
| 511 | $NSNO$ | = | non-submerged notch and orifice fishway |
| 512 | NSO | = | non-submerged orifice fishway |
| 513 | Ort_E | = | orientation of the entrance respect to the river |
| 514 | $Orts$ | = | orientation of the exit respect to the river |
| 515 | $Q_{attraction}$ | = | relative attraction flow (%) |
| 516 | S | = | suitable |
| 517 | SN | = | submerged notch fishway |
| 518 | SNO | = | submerged notch with orifice fishway |
| 519 | SO | = | submerged orifice fishway |
| 520 | T_E | = | type of entrance |
| 521 | T_{Ps} | = | type of connection between pools |
| 522 | T_S | = | type of exit |
| 523 | U | = | unsuitable |
| 524 | VS | = | vertical slots fishway |
| 525 | WFD | = | water Framework Directive (2000/60/EC) |
| 526 | | | |

731 **APPENDIX A**

732 Table A.1. Scores of the assessed variables for the studied stepped fishways in the Duero River basin (VS – vertical slots; SN – submerged notches; SNO – submerged notches
733 with orifices; NSN – non-submerged notches; NSNO – non-submerged notches and orifices; $Q_{attraction}$ – relative flow of attraction; L_E – location of the fish entrance; ΔH – water
734 level difference; D – water depth; b – width for fish pass; Ort – orientation respect to the river; T – type of element for fish pass; D_{prevE} – water depth before the entrance; N –
735 volumetric power dissipation; D_{med} – mean water depth in the pool; D_{postS} – water depth after the exit; E – entry; P_s – passage; S – exit).
